Kachnar (*Bauhinia variegata* L.), locally known as Karali in parts of Himachal Pradesh, is an important seasonal food plant of the Himalayan foothills. Its tender flower buds and flowers are traditionally consumed as vegetables, pickles and other preparations. Besides its culinary importance, Kachnar has attracted scientific interest because of its nutritional constituents, phenolic compounds and potential applications in food processing. However, its short harvesting season limits year-round availability. Drying, powder preparation, incorporation into traditional foods and other preservation techniques offer opportunities for value addition. Sustainable harvesting, correct botanical identification, food safety and species-specific nutritional studies are essential for its wider utilisation. This article highlights the traditional importance, nutritional potential and prospects of Kachnar as a value-added food resource for Himachal Pradesh.

Introduction

The Himalayan foothills of Himachal Pradesh are rich in traditionally consumed wild and underutilised food plants. Among these, Kachnar (*Bauhinia variegata* L.), locally known as Karali, holds a special place in the seasonal food culture of rural communities. During late winter and early spring, its attractive pink and white flowers appear on almost leafless branches. Along with their ornamental beauty, the tender flower buds provide a nutritious seasonal vegetable. Kachnar belongs to the family Fabaceae and is a medium-sized deciduous tree commonly found along field boundaries, forest margins, roadsides and homesteads. Traditionally, its flower buds and flowers are used in vegetable preparations, pickles and other local dishes. The plant is also recognised in traditional medicine, although its medicinal uses should be distinguished from scientifically established health benefits. With increasing interest in traditional foods, local biodiversity and sustainable food systems, Kachnar offers promising opportunities for food processing, product development and rural entrepreneurship.

Traditional Food Uses of Kachnar

In several parts of Himachal Pradesh, tender Kachnar buds are collected during the flowering season and prepared as a vegetable using locally available spices. They are also used in pickles and yoghurt-based preparations. Their slightly firm texture and ability to absorb flavours make them suitable for different culinary applications. The availability of Kachnar is restricted to a few weeks each year. Consequently, harvesting time and the stage of flower development are important factors influencing its quality. Verma et al. (2012) reported that the maturity stage influences the physicochemical and nutritional characteristics of Kachnar green buds and flowers. This indicates that appropriate harvesting practices are important for obtaining good-quality raw material.

Nutritional and Functional Potential

Edible flower buds can contribute dietary fibre, minerals and other plant constituents to the human diet. Research on Kachnar has investigated its nutritional composition and phytochemical characteristics, indicating its potential as an underutilised food resource. Kumar et al. (2020) discussed the phenolic compounds, flavonoids and antioxidant properties associated with Kachnar. These plant compounds have attracted attention because of their potential biological activities. However, antioxidant activity observed under laboratory conditions does not necessarily establish a health benefit in humans. The nutritional composition of Kachnar may vary depending on geographical location, environmental conditions, maturity stage and processing methods. Therefore, detailed nutritional analysis of locally available Kachnar from different regions of Himachal Pradesh would be valuable.

Opportunities for Food Processing and Value Addition

The short availability period of fresh Kachnar is one of the major challenges affecting its wider utilisation. Food processing technologies can help preserve the harvest and increase its economic value.

1. Preparation of Kachnar Powder: Drying and powder preparation offer practical opportunities to extend the availability of Kachnar beyond its natural harvesting season. The dried material can be incorporated into traditional foods and other suitable food formulations. Mazhar et al. (2024) investigated the effects of microwave processing on the nutritional, antinutritional, antioxidant and sensory characteristics of Kachnar powder and supplemented flatbreads. Their research highlights the potential of Kachnar powder as an ingredient for value-added food products. Other drying techniques, including shade drying, hot-air drying and freeze drying, can also be explored to assess their effects on colour, flavour, nutritional quality and storage stability.

2. Development of Value-Added Products: Kachnar can be utilised in several traditional and innovative food products, including:

- Kachnar powder and dried flower buds.
- Kachnar-enriched flatbreads and traditional bakery products.
- Ready-to-cook vegetable mixtures.
- Pickles and seasoning preparations.
- Convenient food mixes containing dried Kachnar.

Such products could create opportunities for small-scale food processing enterprises, self-help groups and rural women entrepreneurs.

3. Improving Processing and Food Quality: Like several plant-based foods, Kachnar may contain antinutritional constituents such as tannins and phytates. Their concentrations and nutritional significance need to be evaluated through appropriate analysis. Traditional cooking methods and modern processing techniques, including blanching, boiling, steaming and drying, could be compared to identify suitable processing conditions. Product development should include nutritional evaluation, sensory testing, microbial analysis and shelf-life assessment to ensure quality and safety.

Sustainable Utilisation and Conservation

Growing commercial interest in Kachnar should be accompanied by responsible harvesting practices. Excessive collection of flower buds may reduce the reproductive potential of trees by affecting subsequent fruit and seed development. Encouraging Kachnar plantation along farm boundaries, community lands and agroforestry systems could help increase its availability while reducing pressure on naturally growing trees. Local communities also possess valuable knowledge regarding the appropriate harvesting stage, traditional recipes and preparation techniques. Documenting this knowledge can support future research and sustainable utilisation. Another important consideration is botanical identification. The common name Kachnar is used for different *Bauhinia* species.

Most importantly, findings related to seed oil from *Bauhinia purpurea* should not automatically be attributed to *Bauhinia variegata*. Species-specific identification and nutritional evaluation are essential for developing reliable food products.

Future Prospects for Himachal Pradesh

Kachnar has considerable potential to become an important regional food resource through the integration of traditional knowledge and modern food science. Research institutions and agricultural universities in Himachal Pradesh can undertake nutritional profiling, identify suitable harvesting stages and evaluate different preservation methods. Development of Kachnar-based products, particularly dried buds, powders, pickles and enriched traditional foods, may provide additional income opportunities for farmers and rural entrepreneurs. Training programmes on hygienic harvesting, scientific drying, packaging and storage could further support small-scale processing activities. However, product development must be supported by appropriate food safety evaluation and standardised processing practices.

Conclusion

Kachnar (Karali) is more than an attractive spring-flowering tree; it is an important part of the traditional food heritage of Himachal Pradesh. Its edible buds and flowers offer opportunities for nutritional utilisation, food processing and rural entrepreneurship. Scientific research on drying, powder preparation and value-added products indicates promising possibilities for extending its seasonal availability. However, further region-specific studies, sustainable harvesting practices and proper food safety evaluation are required. Farmers, researchers and rural communities should work together to conserve Kachnar trees and explore their food-processing potential. Bringing this traditional Himalayan food back into wider use can help conserve local biodiversity, promote traditional diets and create opportunities for sustainable rural development.
